1 Bootloader

1.1 Headers

The disk is ordered into sectors, of size 200_{16} , starting from sector 1[3]. When the BIOS loads the OS, it copies the first sector, which would be the first 512 bytes, from the disk into memory, starting at $7C00_{16}[1]$.

Memory is also ordered into segments, of size $10_{16}[4]$. This means that memory addresses can overlap, for example: The address $0000:7C00_{16}$ is the same as $0700:0C00_{16}$.

You must ensure that the bytes at $1FE_{16}$ and $1FF_{16}$ contain values 55_{16} and AA_{16} respectively[5]. This is called the magic number, and is used to differentiate bootable disks from non-bootable disks.

When the BIOS hands control to the OS, the CPU will be in 16 bit (real) mode[6], which means it is using 16 bits per instruction. This is because the CPU is in 16 bit mode by default. You must ensure that your program code for the bootloader begins in 16 bit (assuming real) mode.

bootloader/main.asm

```
[org 0x7c00] ; memory load location ; real mode
```

1.2 Disk read

Reading from the disk is done with Bios Interrupt 13_{16} ah=02[2].

The interrupt specification is layed out below.1:

Register	Value
AH	02
AL	Number of sectors to read
СН	Cylinder
DH	Head
CL	Sector
DL	Drive
ES:BX	Output offset

Since the DL register is initialised with the boot drive before control is handed to our program[7], as long as it is not overwritten before calling int 13_{16} , you do not have to alter it.

Since the ES register cannot be written to directly, due to no CPU instruction being available to transfer a value to ES[8], which results in an intemediary value needing to be used.

I decided to use BX, due to it being overwritten used in the instruction after, but any unused register will do. Then, I assigned BX with $7e00_{16}$, which

is 200_{16} bytes more than the start of the program[1], which is the precise number of bytes loaded by the BIOS[3].

The number of load segments (register AX)[2] have a limit of around 100 on some systems, and around 70 on QEMU. 64 is a safe number of sectors to load, and allows for 32KB of kernel instructions (which is far more than enough).

Sometimes there will be an error, stored in the carry bit[2], if this happens, retry the load from disk. An error may also be indicated by the AL register having an incorrect number of sectors read.

bootloader/main.asm

```
KERNEL_SEGS equ 64
                                ; KERNEL_SEGS * 512
2
    ; read kernel (https://en.wikipedia.org/wiki/INT_13H)
    mov bx, 0
    mov es, bx
    mov bx, 0x7e00
                                    ; offset
6
    mov ah, 0x02
                                  ; set read mode
    mov cl, 2
                              ; start from sec 2
    mov al, KERNEL_SEGS
                                ; sectors to read
    mov ch, 0
                               ; cylinder
10
    mov dh, 0
                               ; head
11
    int 0x13
                              ; call
12
    ic $$
                                   ; carry bit stores error, loop
13
    cmp al, KERNEL_SEGS
                                 ; al is sectors read
14
    ine $$
                                    ; if all sectors arent read, loop
15
```

1.3 Usable memory

The amount of usable memory varies between systems, and some memory is reserved for hardware, VGA and VBE, console video memory, etc.

Detecting available memory blocks is done with interrupt $15_{16}[12].3$. Although you can probably get away with ignoring this, and just hoping memory above, lets say 1mb, is completely fine, I went through the extra effort to correctly get usable memory.

This area repeatedly calls int 15_{16} , and saves the result, if it is larger than the currently tested memory, in a memory location ironically not tested to see if it is reserved.

The copying and checking is done in two parts due to the fact that the numbers are larger than the 16 bit memory available in real mode.

```
; get largest availible memory block
pusha; push all
mov cx, 0x0; clear cx for addition later
```

```
xor eax, eax
4
    mov es, eax
    mov ebx, 0x0
                                  ; clear
6
    mov edx, 0x534d4150
                                 ; magic value
    memreadloop:
8
            mov eax, 0xe820
                                         ; magic value
            mov ecx, 0x18
                                       ; magic value
10
            mov di, 0x7bd0
                                        ; memory location for buffer
11
                                  ; call function
            int 0x15
12
                            ; increment di by entry size
            add di, cx
13
                            ; (cx is 16 bit cl)
14
    memreadloopvalid:
15
            mov eax, [0x7be0]
                                   ; load type
16
            cmp eax, 1
                                    ; check if 1 (availible memory)
17
             jne memreadloopend
                                    ; go to next otherwise
    memreadloopcheck:
19
            mov eax, [0x7bda]
                                       ; load size of current
20
            mov ecx, [0x7bfa]
                                       ; load size of biggest
21
                                          ; check if bigger
             cmp eax, ecx
22
                                        ; go to next otherwise
             jle memreadloopend
23
    memreadlooprecord:
24
            mov eax, [0x7bd0]
                                       ; load address of current
25
            mov [0x7bf0], eax
                                       ; record biggest address
26
            mov eax, [0x7bd4]
                                       ; load address of current
27
            mov [0x7bf4], eax
                                       ; record biggest address
28
            mov eax, [0x7bd8]
                                       ; load size of current
29
            mov [0x7bf8], eax
                                       ; record biggest size
30
            mov eax, [0x7bdc]
                                       ; load size of current
31
            mov [0x7bfc], eax
                                       ; record biggest size
32
    memreadloopend:
33
            cmp ebx, 0
                                        ; check if next
34
             jnz memreadloop
                                              ; repeat
35
```

1.4 Display

1.4.1 VGA

Enabling VGA[14] here allows me to get the font later, and also serves as compatibility for if VESA is not supported.

The options for AL are defined.4.

```
; vga mode
mov ah, 0x0 ; graphics mode
```

```
mov al, 0x13 ; 256 colour 200x320 int 0x10 ; set vga mode
```

1.4.2 Font

The code below gets the font from the VGA card. This is so I did not have to store my own.

The code is taken mostly from this OsDev page[13], due to the fact that I figured it was mostly copy paste anyway.

bootloader/main.asm

```
; get vga font
2
    mov eax, 0x100
    mov es, eax
    mov ax, 0x0
    mov di, ax
    push ds
    push es
    mov ax, 0x1130
                                      ; magic numbers
    mov bh, 0x6
    int 0x10
                               ; get vga font
10
    ;mov ds, es
11
    push es
12
    pop ds
13
    pop es
14
15
    mov si, bp
    mov cx, 0x400
16
    rep movsd
17
    pop ds
18
```

1.4.3 VBE

The VESA bios extensions allows for greater colour depth (RGB) and higher resolutions than VGA. Getting the VBE table is done with interrupt $10_{16}[15]$.

Once sifted to find the right function, it can again be enabled with interrupt 10_{16} , the magic numbers for each function are in the VBE spec[15].

The resulting values (whether 24 bit or 32 bit colour is used, the location of the framebuffer, whether VBE is even supported in the first place, etc), are placed into another (not checked) area of memory, which will be used by the kernel later.

I start by checking for VBE2 support, and if it doesn't exist I jump to the end of the VBE section. Then I go through each function, checking if it has RGB colourspace, and is the correct resolution. I then update the bytes at some position (again not fully checked) so my kernel has access to whether VBE was

enabled or not, and also to provide the kernel with the position of the linear framebuffer.

This is due to the fact that in VBE2, it is not required that all the VBE1 functions.5 are supported (even though they most likely are).

Enabling a VBE mode is as simple as VBE once the functions have been sorted, and is the same BIOS interrupt.6.

```
; get vesa support
    mov [0x2000], DWORD "VBE2"
2
    mov ax, 0x4f00
                                 ; magic number
    mov di, 0
    mov es, di
                                 ; offset to table
    mov di, 0x2000
    int 0x10
                          ; get vbe table
                             ; check if support
    cmp ax, 0x004f
                               ; use vga instead if not
    jne skip_vbe
10
    mov di, 0
                           ; offset to tmp
11
   mov es, di
12
                                ; segment to tmp
    mov di, 0x2200
13
    mov si, [0x2000 + 16]
                               ; segment of list
14
    mov ds, si
15
    mov si, [0x2000 + 14]
                               ; offset of list
16
17
    vbe_loop:
    ; get next supported vesa function
19

73
```

1.5 Enabling 32-bit processing

1.5.1 Segment descriptor

The Global Descriptor Table is necessary for enabling protected mode[9], and is defined below in a basic form in order to switch to protected mode.

For my kernel, none of the features of the GDT, like paging[11], are not needed, so the GDT is very basic.2.

bootloader/main.asm

```
jmp gdt_after
1
2
    ; segment descriptor (reverse order)
    gdt_start:
4
                                  ; null byte start
             dq 0
    gdt_code:
6
                               ; segment limit
             dw Oxffff
                              ; segment base
            db 0,0,0
                                   ; flags (see wiki)
             db 0b10011010
9
             db 0b11001111
                                   ; 4b flags (see wiki) + seg limit
10
             db 0
                                  ; segment base
11
    gdt_data:
12
                               ; segment limit
            dw Oxffff
13
            db 0,0,0
                              ; segment base
14
                                   ; flags (see wiki)
             db 0b10010010
15
             db 0b11001111
                                   ; 4b flags (see wiki) + seg limit
16
             db 0
                                  ; segment base
17
    gdt_end:
             dw gdt_end - gdt_start - 1
                                                 ; limit
19
                                                   ; addr 24 bit
             dd gdt_start
20
    gdt_after:
21
```

1.5.2 Prerequisites

To enable protected mode, you must first disable interrupts, and load the global descriptor table[16], which can be done in NASM with commands cli and lgdt [GDT ADDRESS] respectively.

bootloader/main.asm

```
cli ; disable interrupts
lgdt [gdt_end] ; gdt_end is descritor table

descriptor
```

1.5.3 Protected mode

Upon the completion of all the above, you can then set bit 0 (starting from 0) to 1 in the control register CR0[16], which must be done in seperate commands, as the special register CR0 is not directly assignable[8].

You must then immediately [16] perform a long jump to your next desired instruction.

You then have to tell the assembler that you are now using 32 bits, which can be done with the [bits 32] command in NASM.

bootloader/main.asm

```
mov eax, cr0
1
   or eax, 1
                              ; set 1 bit in control register for
2
    \rightarrow protected mode
   mov cr0, eax
3
   jmp (gdt_code - gdt_start):bits32code
                                                    ; stall cpu and
    → flush all cache (as moving to different segment) to finalize
       protected mode
5
   ; finally 32 bits
   [bits 32]
   bits32code:
```

1.6 Enabling the A20 line

Enabling the A20 line (the proper way) is by the keyboard[10]. This is incredibly tedious and repetitive, which is why I have taken this code from the OsDev page.

Two small assembly functions: a20wait; a20waitr, have been created to avoid some of the repetition. a20wait will repeatedly poll port 64_{16} until bit 1 is set (which is why TEST is used). a20waitr will do the same until bit 0 is set.

This is due to the fact that it is required to wait for bit 1 in port 64_{16} before writing and bit 0 in port 64_{16} before reading.

A brief outline of the functions of the A20 line are provided within this document.7.

```
xor al, al
    call a20wait
                                  ; wait for write
2
    mov al, 0xad
3
    out 0x64, al
                                  ; send Oxad
    call a20wait
                                  ; wait for write
    mov al, 0xd0
    out 0x64, al
                                  ; send OxdO
                                   ; wait for read
    call a20waitr
    in al, 0x60
                                 ; get ack
9
    push eax
    call a20wait
                                  ; wait for write
11
    mov al, 0xd1
12
    out 0x64, al
                                  ; send Oxd1
13
    call a20wait
                                  ; wait for write
                                     ; eax gets overwritten
    pop eax
15
    or al, 0b0010
                                   ; a20 bit
    out 0x60, al
                                  ; set a20 bit on
17
    call a20wait
                                  ; wait for write
```

```
mov al, Oxae
19
     out 0x64, al
                                    ; send Oxae
20
     call a20wait
                                    ; wait for generic
21
     jmp skipa20
                                   ; go to end
     a20wait:
23
             in al, 0x64
24
             test al,2
25
              jnz a20wait
26
             ret
27
     a20waitr:
28
             in al, 0x64
29
             test al,1
30
             jz a20waitr
31
             ret
32
33
     skipa20:
34
```

1.7 Loading the Kernel

Before loading the kernel, I initialise all the registers high parts with the segment and move the stack pointers to 7000_{16} .

The bootloader begins at $7c00_{16}[1]$, and because the stack grows downwards, 7000_{16} is a perfect location for a stack. You can place yours where you like.

```
jmp (gdt_code - gdt_start):start_kernel
2
    start_kernel:
3
              ; segment registers init
             mov ax, gdt_data - gdt_start
5
             mov ds, ax
6
             mov es, ax
             {\tt mov} fs, {\tt ax}
             mov gs, ax
9
             mov ss, ax
10
11
              ; stack pointers
             mov esp, 0x7000
                                                 ; top of stack
13
             mov ebp, esp
                                              ; bottom of stack
14
15
              call kernel
                                             ; start kernel and move back
16
              \hookrightarrow to segment
17
     ; kernel
18
    kernel:
19
```

```
jmp kernel_loadseg
                                         ; hand control to kernel
20
                                             ; return -> error, loop
             jmp $$
21
22
24
     ; kernel load
25
    kernel_loadseg:
26
    call kernel_cseg
27
    jmp $
                                            ; if fail restart
28
    kernel_cseg:
                                           ; compiled c appeneded here
```

1.8 The boot signature

You must ensure that the bytes at $1FE_{16}$ and $1FF_{16}$ contain values 55_{16} and AA_{16} respectively[5]. This is called the boot signature, or magic number, and is used to differentiate bootable disks from non-bootable disks, and also tells the BIOS how to load your OS.

```
; padding
times 510 - ($-$$) db 0

; boot signature
db 0x55,0xaa
```

2 Appendix

.1 INT 13₁₆ AH 02₁₆

Register	Value
AL	Number of sectors to read
СН	Cylinder
DH	Head
CL	Sector
DL	Drive
ES:BX	Output offset

.2 Segment Descriptor

Bits	Segment	Value
0-15	(1)	Segment limit
16-39	(1)	Segment base
40-43	(flag)	Type
44	(flag)	S
45-46	(flag)	DPL
47	(flag)	P
48-51	(2)	Segment limit
52	(flag)	A
53	(null)	0
54	(flag)	DB
55	(flag)	G
56-63	(2)	Segment base

.3 INT 15₁₆ EAX E820₁₆

Register	Value
EAX	$E820_{16}$
EBX	0
ECX	24
EDX	$534D4150_{16}$
ES:DI	Output buffer

.4 VGA Options

Value	Type	Resolution	Colourspace
0016	Text	40x25	1
01 ₁₆	Text	40x25	16
02 ₁₆	Text	80x25	1
03 ₁₆	Text	80x25	16
04 ₁₆	CGA	320x200	4
0516	CGA	320x200	1
0616	CGA	640x200	2
07 ₁₆	MDA	80x25	1
$0D_{16}$	EGA	320x200	16
$0E_{16}$	EGA	640x200	16
0F ₁₆	EGA	640x350	1
10 ₁₆	EGA	640x350	16
11 ₁₆	VGA	640x480	1
12 ₁₆	VGA	640x480	16
13 ₁₆	VGA	320x200	256

.5 VBE1 Functions

Value	Type	Resolution	Colourspace
100_{16}	Graphics	640x400	256
101_{16}	Graphics	640x480	256
103_{16}	Graphics	800x600	256
104 ₁₆	Graphics	1024x768	16
105_{16}	Graphics	1024x768	256
